(54) Title: PRODUCTION OF ANTIBODIES OR (FUNCTIONALIZED) FRAGMENTS THEREOF DERIVED FROM HEAVY CHAIN IMMUNOGLOBULINS OF CAMELIDAE			
(57) Abstract			
<p>A process is provided for the production of an antibody or a fragment or functionalized fragment thereof using a transformed lower eukaryotic host containing an expressible DNA sequence encoding the antibody or (functionalized) fragment thereof, wherein the antibody or (functionalized) fragment thereof is derived from a heavy chain immunoglobulin of <i>Camelidae</i> and is devoid of light chains, and wherein the lower eukaryotic host is a mould, preferably belonging to the genera <i>Aspergillus</i> or <i>Trichoderma</i>, or a yeast, preferably belonging to the yeast genera <i>Saccharomyces</i>, <i>Kluyveromyces</i>, <i>Hansenula</i>, or <i>Pichia</i>. The heavy chain fragment can contain at least the whole variable domain. A complementary determining region (CDR) different from the CDR belonging to the natural antibody ex <i>Camelidae</i> can be grafted on the framework of the variable domain of the heavy chain immunoglobulin. The catalytic antibodies can be raised in <i>Camelidae</i> against transition state molecules. The functionalized antibody or fragment thereof can comprise a fusion protein of both a heavy chain immunoglobulin from <i>Camelidae</i> or a fragment thereof and another polypeptide, e.g., an enzyme, preferably an oxido-reductase. Also provided are new products obtainable by a process as described, and compositions containing a product produced by a process as described, which composition may contain a new product as provided.</p>

Title:     **Production of antibodies or (functionalized) fragments thereof derived from heavy chain immunoglobulins of *Camelidae***

The present invention relates to a process for the production of antibodies or  
5 (functionalized) fragments thereof derived from heavy chain immunoglobulins of *Camelidae* and is partly based on research investigations carried out at the Free University of Brussels. A draft publication thereon already submitted to the periodical Nature and communicated to the present applicants by Prof. R. Hamers reads as follows.

10

### **FUNCTIONAL HEAVY CHAIN IMMUNOGLOBULINS IN THE CAMELIDS**

Random association of  $V_L$  and  $V_H$  repertoires contributes considerably to antibody diversity (1). The diversity and the affinity are then increased by hypermutation in  
15 B-cells located in germinal centres (2). Except in the heavy chain disease (3), naturally occurring heavy chain antibodies have not been described, although antigen binding has been demonstrated for separated heavy chains (4) or cloned  $V_H$  domains (5). The presence of considerable amounts IgG like material of 100 Kd in the serum of the camel (*Camelus dromedarius*) (6) was confirmed. These molecules  
20 are composed of heavy chain dimers and are devoid of light chains. Nevertheless they bear an extensive antigen binding repertoire, a finding which questions the role of the light chains in the camel. Camel heavy chain IgGs lack the  $C_H1$ , which in one IgG class might be structurally replaced by an extended hinge. Heavy chain IgGs are a feature of all camelids. These findings open perspectives in engineering of  
25 antibodies.

By a combination of affinity chromatography on Protein A and Protein G, three quantitatively important fractions corresponding to subclasses of IgG can be isolated from the serum of camels (*Camelus dromedarius*) (Fig. 1A, lanes c-f).

30 One fraction ( $IgG_1$ ) contains molecules of 170 Kd (Fig. 1B, lane 2) which upon reduction yield 50 Kd heavy chains and large 30 kD light chains (Fig. 1C, lane 2). The two other immunoglobulin fractions contain molecules of approximately 100 Kd

(Fig. 1B, lanes 1 and 3) which upon reduction yield only heavy chains of respectively 46 Kd (IgG<sub>2</sub> fraction binding only to Protein A) (Fig. 1C, lane 3) and 43 Kd (IgG<sub>3</sub> fraction binding to Protein A and Protein G) (Fig. 1C, lane 1). These two IgG classes appear to lack the light chain completely.

5

To exclude the possibility that the light chains were only weakly associated with the heavy chains and lost during the selective purification, whole serum was size fractionated by gel filtration. Coomassie blue staining of unreduced fractions revealed the sequential elution of the 170 Kd IgG<sub>1</sub> followed by the incompletely resolved isotypes IgG<sub>2</sub> and IgG<sub>3</sub> (90 Kd) (Fig. 1D, upper inset). Immunostaining of  
10 the same fractions after reduction confirmed that the light chains were present solely in the 50 Kd heavy chain containing fractions (Fig. 1D, lower inset).

A comparative study of old world camelids (*Camelus bactrianus* and *Camelus dromedarius*) and new world camelids (*Lama pacos*, *Lama glama* and *Lama vicugna*)  
15 showed that heavy chain immunoglobulins are abundant in the sera of all species examined (data not shown) and total up to 75% of the molecules binding to protein A.

The abundance of the heavy chain immunoglobulins in the serum of camelids raises  
20 the question as to whether they bear an extensive antigen binding repertoire. This question could be answered by examining the IgG<sub>1</sub>, IgG<sub>2</sub> and IgG<sub>3</sub> fractions from the serum of camels (*Camelus dromedarius*) with a high antitrypanosome titer (7). In radio-immunoprecipitation, purified fractions of IgG<sub>1</sub>, IgG<sub>2</sub> and IgG<sub>3</sub> derived from infected camels were shown to bind a large number of antigens present in a <sup>35</sup>S  
25 methionine labelled trypanosome lysate (Fig. 2A), indicating an extensive repertoire complexity for the three IgG classes. Conversely, in blotting experiments, <sup>35</sup>S methionine labelled trypanosome lysate binds to SDS-PAGE separated IgG<sub>1</sub>, IgG<sub>2</sub> and IgG<sub>3</sub> obtained from infected animals (Fig. 2B). These findings indicate that the heavy chains alone can generate an extensive repertoire and question the obligatory  
30 contribution of the light chain to the useful antibody repertoire in the camelids.

The camelid  $\gamma 2$  and  $\gamma 3$  chains are considerably shorter than the normal mammalian  $\gamma$  or camel  $\gamma 1$  chains. This would suggest that, as in the case of heavy chain disease (3), deletions have occurred in the  $C_{H1}$  protein domain (8,9). To address this question, cDNA was synthesized from camel spleen mRNA and the sequences  
5 between the 5' end of the  $V_{H1}$  and the  $C_{H2}$  were amplified by a Polymerase Chain Reaction (PCR), and cloned. Seventeen clones presenting a different  $V_H$  sequence were isolated and sequenced. Their most striking feature was the complete lack of the  $C_{H1}$  domain, the last framework (FR4) residues of the  $V_H$  region being immediately followed by the hinge (Fig. 3, lower part). The absence of the  $C_{H1}$  domain  
10 clarifies two important dilemmas.

First, immunoglobulin heavy chains are normally not secreted unless the heavy chain chaperoning protein or BIP (10) has been replaced by the L chain (11), or alternatively the  $C_{H1}$  domain has been deleted (3,8,9). Secondly, isolated heavy  
15 chains from mammalian immunoglobulins tend to aggregate, but are only solubilized by light chains (8,12) which bind to the  $C_{H1}$  and the  $V_H$  domains (13).

14 of the 17 clones were characterized by a short hinge sequence with a length equal to that of human  $IgG_2$  and  $IgG_4$  (14) (Fig. 3). The other 3 had a long hinge  
20 sequence containing the 'EPK' hinge motif found in human  $IgG_1$  and  $IgG_3$  (14). They possess the  $C_{H2}$  'APELL/P' motif also found in human  $IgG_1$  and  $IgG_3$  (see SEQ. ID. NO: 1-2), and which is associated with mammary transport of bovine  $IgG_1$  (15). On basis of molecular weight, we expect the "short hinge" clones to correspond to  $IgG_3$  and the "long hinge" clones to  $IgG_2$ .

25 In the short hinge containing antibody, the extreme distance between the extremities of the  $V_{H1}$  regions will be of the order of 80 Å corresponding to twice the size of a single domain of 40 Å ( $2 \times V_{H1}$ ) (16). This could be a severe limitation for agglutinating, cross linking or complement fixation (17,18). In the long hinge containing  
30 immunoglobulin the absence of  $C_{H1}$  might be compensated by the extremely long hinge itself, composed of a 12 fold repeat of the sequence Pro-X (X=Gln, Glu, Lys) (Fig. 3 & 4). NMR (19) and molecular modelling (20) of Pro-X repeats present in

the TonB protein of *E. coli* (X=Glu, Lys) and the membrane procyclin of trypanosomes (X=Asp, Glu) indicate that these repeated sequences function as rigid rodlike spacers with a diameter of 8 Å and a rise of 2.9 Å per residue. Assuming the same geometry, the long hinge would be 70 Å which compensates for the absence of the C<sub>H</sub>1 domain.

The binding site of heavy chain antibodies cannot form the pocket resulting from adjoining light and heavy chain V regions and the residues of the V<sub>H</sub> which normally interact with V<sub>L</sub> will be exposed to solvent (3,5,13). It was found that leucine at position 45 conserved in 98% of human and murine V<sub>H</sub> sequences (14), and crucial in the V<sub>H</sub>-V<sub>L</sub> association (13), can be replaced by an arginine (Fig. 3, upper part). This substitution is in accordance with both the lost contact with a V<sub>L</sub> domain and an increased solubility.

Unlike myeloma heavy chains which result mainly from C<sub>H</sub>1 deletion in a single antibody producing cell (21) the camelid heavy chain antibodies have emerged in a normal immunological environment and it is expected that they will have undergone the selective refinement in specificity and affinity accompanying B cell maturation (1, 2). The obtention of camelid heavy chain antibodies could therefore be an invaluable asset in the development and engineering of soluble V<sub>H</sub> domains (5) or of new immunologicals for diagnostic, therapeutic or biochemical purposes.

**Figure 1 Characterisation and purification of camel IgG classes on Protein A, Protein G and gel filtration.**

- (A) The fraction of *C. dromedarius* serum adsorbed on Protein A shows upon reduction on SDS-PAGE three heavy chain components of respectively 50, 46, and 43 Kd (bands between dots), absent in the non adsorbed fraction (lane d), and light chain components of around 30 Kd (lane c) considerably larger than rabbit light chain (lane a, rabbit IgG). The fractions adsorbed on Protein G (lane e) lack the 46 Kd heavy chain which remains in the non adsorbed fraction (lane f). Lane b contains a size marker.
- 10 (B and C) By differential adsorption and elution on Protein G and Protein A, the IgG fractions containing 43 Kd (lane 1), 46 Kd (lane 3) and 50 Kd (lanes 2) heavy chains were purified and analysed on SDS-PAGE in absence (B) or presence (C) of DTT.
- (D) Whole camel serum (0.1 ml) was fractionated by gel filtration on a Superdex 200 column using 150 mM NaCl, 50 mM sodium phosphate buffer pH 7.0 as eluent. Affinity purified IgG<sub>2</sub> and IgG<sub>3</sub> elute at the positions indicated by arrows. The fractions of interest were further analysed by SDS-PAGE with or without prior reduction. The protein contents as visualized by Coomassie blue (without reduction, upper inset) are compared with the immunoglobulins from the same fractions (after reduction with DTT, lower inset) as revealed by Western blotting with a rabbit anti-camel-IgG (lower inset).
- 15  
20

**METHODS.** 5 ml of *C. dromedarius* serum is adsorbed onto a 5 ml Protein G Sepharose (Pharmacia) column, and washed with 20 mM phosphate buffer, pH 7.0. Upon elution with 0.15 M NaCl, 0.58 % acetic acid (pH 3.5), IgG<sub>3</sub> of 100 Kd is eluted which upon reduction yields heavy chains of 43 Kd (lane 1, B and C). IgG<sub>1</sub> of 170 Kd can subsequently be eluted with pH 2.7 buffer (0.1 M Gly-HCl). This fraction, upon reduction, yields a 50 Kd heavy chain and a broad light chain band (lane 2, C). The fraction not adsorbed on Protein G is brought on a 5 ml Protein A Sepharose column. After washing and elution with 0.15 M NaCl, 0.58% acetic acid (pH 4.5) IgG<sub>2</sub> of 100 Kd is obtained which consists solely of 46 Kd heavy chains (lane 3, C).

25  
30

**Figure 2** Repertoire complexity and antigen binding capacity of camel IgG<sub>1</sub>, IgG<sub>2</sub> and IgG<sub>3</sub> analysed by radioimmunoprecipitation (A) or Western blotting (B & C).

- (A) Serum or purified IgG fractions from healthy or *Trypanoma evansi* infected *C. dromedarius* (CATT titer 1/160 (7)) were incubated with labelled trypanosome lysate, recovered with Protein A Sepharose and analysed by SDS-PAGE. The relative counts recovered are inscribed below each lane. No trypanosome proteins bind to the Protein A or to the healthy camel immunoglobulins.
- 10 (B) 20 µg of IgG<sub>1</sub>, IgG<sub>2</sub> and IgG<sub>3</sub> from healthy and trypanosome infected animals were separated by SDS-PAGE without prior reduction or heating. The electroblotted proteins were incubated with the labelled trypanosome lysate. The IgG<sub>2</sub> shows a single antigen binding component corresponding to the heavy chain immunoglobulin whereas the IgG<sub>3</sub> fraction appears to contain in addition two larger antigen binding components barely detectable by Ponceau Red staining (C). These are possibly Ig classes copurified as immunocomplexes present in the serum of the infected animals.

**METHODS.** (<sup>35</sup>S)-methionine labelled *Trypanosoma evansi* lysate (500,000 counts) (22) was incubated (4°C, 1 hour) with 10 µl of serum or, 20 µg of IgG<sub>1</sub>, IgG<sub>2</sub> or IgG<sub>3</sub> in 200 µl of 0.4 M NaCl, 10 mM EDTA, 10 mM Tris (pH 8.3), containing 0.1 M TLCK. 10 mg of Protein A Sepharose suspended in 200 µl of the same buffer was added (4°C, 1 hour). After washing and centrifugation, each pellet was resuspended in 75 µl SDS PAGE sample solution containing DTT, and heated for 3 min. at 100°C. After centrifugation, 5 µl of the supernatant was saved for radioactivity counting and the remainder analysed by SDS PAGE and fluorography.

The nitrocellulose filter of the Western blot of purified fractions IgG<sub>1</sub>, IgG<sub>2</sub> and IgG<sub>3</sub> was stained with Ponceau Red (C) or incubated with 1% ovalbumin in TST buffer (Tris 10 mM, NaCl 150 mM, Tween 0,05%) (B). The membrane was extensively washed with TST buffer and incubated for 2 hours with (<sup>35</sup>S)-labelled trypanosome antigen. To avoid unspecific binding, the labelled trypanosome antigen

lysate was filtered (45  $\mu$ ) and incubated with healthy camel immunoglobulin and ovalbumin adsorbed on a nitrocellulose membrane.

**Figure 3 Amino acid sequences of the V<sub>H</sub> framework, and hinge/C<sub>H</sub>2 of *Camelus dromedarius* heavy chain immunoglobulins, compared to human (italic) V<sub>H</sub> framework (subgroup III) and hinges of human IgG (14).**

METHODS. Total RNA was isolated from a dromedary spleen (23). mRNA was purified with oligo T-paramagnetic beads (PolyATract-Promega). 1  $\mu$ g mRNA was used for preparing double-strand cDNA (23) after an oligo-dT priming using enzymes provided by Boehringer Mannheim. 5  $\mu$ g of cDNA was amplified by PCR in a 100  $\mu$ l reaction mixture (10mM Tris-HCl pH 8.3, 50 mM KCl, 15 mM MgCl<sub>2</sub>, 0.01% (w/v) gelatine, 200  $\mu$ M of each dNTP). 25 pmoles of each oligonucleotide of the mouse V<sub>H</sub> (24), containing a XhoI site, and 5'-CGCCATCAAGGTACCAGT-TGA-3' (see SEQ. ID. NO: 3) were used as primers. The 3' end primer was deduced from partial sequences corresponding to  $\gamma$  chain amino acid 296 to 288 (T. Atarhouch, C. Hamers-Casterman, G. Robinson, private communication) in which one mismatch was introduced to create a KpnI restriction site. After a round of denaturing annealing (94°C for 5 min. and 54°C for 5 min.), 2 U of Taq DNA polymerase were added, to the reaction mixture before subjecting it to 35 cycles of amplification (5). The PCR products were purified by phenol-chloroform extraction followed by HPLC (Genpak-fax column, Waters) and finally by MERMAID (BIO 101, Inc.). After these purification steps, the amplified cDNA was digested with XhoI and KpnI, and ligated into pBluescript.

The clones were sequenced by the dideoxy chain termination method (25). The sequences were translated into amino acids which allowed their assignment to well defined domains of the Ig molecule (14); see SEQ. ID. NO: 4-12

**Figure 4 Schematic representation of the structural organisation of the camel immunoglobulins (adapted from 26).**

On the basis of size consideration, the IgG<sub>1</sub> fraction possess probably the normal antibody assembly of two light and two heavy chains. IgG<sub>3</sub> would have a hinge comparable in size to the human IgG<sub>1</sub>, IgG<sub>2</sub> and IgG<sub>4</sub>. The two antigen binding sites

are much closer to each other as this camel IgG lacks the C<sub>H</sub>1 domain. In the camel IgG<sub>2</sub> the long hinge, being formed of Pro-X repeats (X = Glu, Gln or Lys), most likely adopt a rigid structure (19,20). This long hinge could therefore substitute the C<sub>H</sub>1 domain and bring the two antigen binding sites of IgG<sub>2</sub> to normal positions.

--- End of Draft publication ---

### Background of the invention

Already at a very early stage during evolution antibodies have been developed to protect the host organisms against invading molecules or organisms. Most likely one of the earliest forms of antibodies must have been developed in *Agnatha*. In these primitive fishes antibodies of the IgM type consisting of heavy and light chains have been detected. Also in many other forms of life ranging from amphibians to mammals antibodies are characterized by the feature that they consist of two heavy and two light chains, although the heavy chains of the various classes of immunoglobulins are quite different. These heavy and light chains interact with each other by a number of different physical forces, but interactions between hydrophobic patches present on both the heavy and light chain are always important. The interaction between heavy and light chains exposes the complementarity determining regions (CDRs) of both chains in such a way that the immunoglobulin can bind the antigen optimally. Although individual heavy or light chains have also the capability to bind antigens (Ward *et al.*, Nature 341 (1989) 544-546 = ref. 5 of the above given draft publication) this binding is in general much less strong than that of combined heavy and light chains.

Heavy and light chains are composed of constant and variable domains. In the organisms producing immunoglobulins in their natural state the constant domains are very important for a number of functions, but for many applications of antibodies in industrial processes and products their variable domains are sufficient. Consequently many methods have been described to produce antibody fragments.

30

One of these methods is characterized by cleavage of the antibodies with proteolytic enzymes like papain and pepsin resulting in (a) antibody fragment comprising a light

chain bound via an S-S bridge to part of a corresponding heavy chain formed by proteolytic cleavage of the heavy chain (Fab), or (b) a larger fragment of the antibody comprising two of these Fabs still connected to each other via an S-S bridge in enlargements of the heavy chain parts, indicated with  $F(ab)_2$ , respectively  
5 (see patent applications EP-A-0125023 (GENENTECH / Cabilly *et al.*, 1984) and WO-A-93/02198 (TECH. RES. CENT. FINLAND / Teeri *et al.*, 1993) for definitions of these abbreviations). The disadvantage of the enzymatic route is that the production of whole antibodies is expensive and the enzymatic processing increases the costs of these fragments even more. The high costs of antibody fragments block  
10 the application of these fragments in processes and products outside the pharmaceutical industry.

Another method is based on linkage on DNA level of the genes encoding (parts of) the heavy chain and the light chain. This linkage and the subsequent production of  
15 these chimeric immunoglobulins in microorganisms have been described (for Fab fragments see e.g. Better *et al.*, Science 240 (1988) 1041-1043, for  $F_v$  fragments (combination of variable fragments of the heavy chain ( $V_H$ ) and light chain ( $V_L$ ) still connected to each other by non-covalent binding interactions) see e.g. Skerra *et al.*, Science 240 (1988) 1938, and for single chain  $F_v$  fragments ( $ScF_v$ ; an  $F_v$  fragment in  
20 which the two variable fragments are linked to each other by a linker peptide) see e.g. Bird *et al.*, Science 242 (1988) 423-426. Provided that an appropriate signal sequence has been placed in front of the single chain  $V_H$  and  $V_L$  antibody fragment ( $ScF_v$ ), these products are translocated in *E. coli* into the periplasmic space and can be isolated and activated using quite elaborate and costly procedures. Moreover the  
25 application of antibody fragments produced by *E. coli* in consumer products requires extensive purification processes to remove pyrogenic factors originating from *E. coli*. For this and other reasons the production of  $ScF_v$  in microorganisms that are normally used in the fermentation industry, like prokaryotes as *Streptomyces* or *Bacillus* (see e.g. Wu *et al.* Bio/Technology 11 (1993) 71) or yeasts belonging to the  
30 genera *Saccharomyces* (Teeri *et al.*, 1993, *supra*), *Kluyveromyces*, *Hansenula*, or *Pichia* or moulds belonging to the genera *Aspergillus* or *Trichoderma* is preferred. However with a very few exceptions the production of  $ScF_v$  antibodies using these systems

proved to be impossible or quite poor. Although the exact reasons for the poor production are not well known, the use of linkers between the  $V_H$  and  $V_L$  chains not designed for secretion (Teeri *et al.*, 1993, *supra*) may be a reason.

5 Another reason may be incorrect folding of  $ScF_v$ . The frameworks and to a limited extend the CDRs of variable domains of light and heavy chains interact with each other. It has been described by Chothia *et al.* (J. Mol. Biol. 186 (1985) 651-663 = ref. 13 of the above given draft publication) that this interaction involves amino acids at the following positions of the variable region of the heavy chain: 35, 37, 39,  
10 44-45, 47, 100-103 and 105 (numbering according to Kabat *et al.*, In "*Sequences of Proteins of Immunological Interest*", Public Health Service, NIH, Washington DC, 1983 = ref. 14 of the above given draft publication). Especially leucine at position 45 is strongly conserved and the whole apolar side chain of this amino acid seems to be involved in the interaction with the light chain. These strong interactions may  
15 fold the  $ScF_v$  into a structure that can not be translocated in certain types of lower eukaryotes.

Thus the use of a linker in the production of  $ScF_v$  for connecting a  $V_H$  chain to a  $V_L$  chain, might negatively influence either the translocation, or the folding of such  $ScF_v$ ,  
20 or both.

Not prior-published European patent application 92402326.0 filed 21.08.92 (C. Casterman & R. Hamers) discloses the isolation of new animal-derived immunoglobulins devoid of light chains (also indicated as heavy chain immunoglobulins),  
25 which can especially originate from animals of the camelid family (*Camelidae*). This European patent specification, now publicly available as EP-A1-0 584 421, is incorporated herein by reference. These heavy chain immunoglobulins are characterized in that they comprise two heavy polypeptide chains sufficient for the formation of one or more complete antigen binding sites, whereby a complete antigen binding  
30 site means a site which will alone allow the recognition and complete binding of an antigen, which can be verified by any known method regarding the testing of the binding affinity. The European patent specification further discloses methods for

isolating these heavy chain immunoglobulins from the serum of *Camelidae* and details of the chemical structure of these heavy chain immunoglobulins. It also indicates that these heavy chain immunoglobulins and derivatives thereof can be made by using recombinant DNA technology in both prokaryotes and eukaryotes. The  
5 present invention relates to a further development of the work disclosed in that prior-filed but not prior-published European specification.

Due to the absence of light chains in most of the immunoglobulins of *Camelidae* such linkers are not necessary, thereby avoiding the above-mentioned potential  
10 problems.

As described above in the draft publication for Nature, now publicly available as Nature 363 (3 June 1993) 446-448, and in the not prior-published European patent application 92402326.0 (*supra*) it was surprisingly found that the majority of the protein A-binding immunoglobulins of *Camelidae* consists just of two heavy chains  
15 and that these heavy chains are quite different from common forms of heavy chains, as the C<sub>H</sub>1 domain is replaced by a long or short hinge (indicated for IgG<sub>2</sub> and IgG<sub>3</sub>, respectively, in Figure 4 of the above given draft publication for Nature).

Moreover these heavy chains have a number of other features that make them remarkably different from the heavy chains of common immunoglobulins.

20 One of the most significant features is that they contain quite different amino acid residues at those positions involved in binding to the light chain, which amino acids are highly conserved in common immunoglobulins consisting of two heavy and two light chains (see Table 1 and SEQ. ID. NO: 13-31).

30

For example, according to Pessi *et al.* (1993) a subdomain portion of a V<sub>H</sub> region of  
common antibodies (containing both heavy chains and light chains) is sufficient to  
direct its folding, provided that a cognate V<sub>L</sub> moiety is present. Thus it might be  
35 expected from literature on the common antibodies that without V<sub>L</sub> chains proper  
folding of heavy chains cannot be achieved. A striking difference between the  
common antibodies and the *Camelidae*-derived heavy chain antibodies is, that the  
highly conserved apolar amino acid leucine (L) at place 45 present in common  
antibodies is replaced in most of the *Camelidae*-derived heavy chain antibodies by  
40 the charged amino acid arginine (R), thereby preventing binding of the variable  
region of the heavy chain to that of the light chains.

Another remarkable feature is that one of the CDRs of the heavy chains of this type  
of immunoglobulins from *Camelidae*, CDR3, is often much longer than the

corresponding CDR3 of common heavy chains. Besides the two conserved cysteines forming a disulphide bridge in common V<sub>H</sub> fragments, the *Camelidae* V<sub>H</sub> fragments often contain two additional cysteine residues, one of which often is present in CDR3.

- 5 According to the present inventors these features indicate that CDR3 may play an important role in the binding of antigens by these heavy chain antibodies and can compensate for the absence of light chains (also containing CDRs) in binding of antigens by immunoglobulins in *Camelidae*.

Thus, as the heavy chains of *Camelidae* do not have special features for interacting  
10 with corresponding light chains (which are absent), these heavy chains are very different from common heavy chains of immunoglobulins and seem intrinsically more suitable for secretion by prokaryotic and lower eukaryotic cells.

The present inventors realized that these features make both intact heavy chain  
15 immunoglobulins of *Camelidae* and fragments thereof very attractive for their production by microorganisms. The same holds for derivatives thereof including functionalized fragments. In this specification the term "functionalized fragment" is used for indicating an antibody or fragment thereof to which one or more functional groups, including enzymes and other binding polypeptides, are attached resulting in  
20 fusion products of such antibody fragment with another biofunctional molecule.

#### Summary of the invention

In a broad sense the invention provides a process for the production of an antibody or a fragment or functionalized fragment thereof using a transformed lower  
25 eukaryotic host containing an expressible DNA sequence encoding the antibody or (functionalized) fragment thereof, wherein the antibody or (functionalized) fragment thereof is derived from a heavy chain immunoglobulin of *Camelidae* and is devoid of light chains, and wherein the lower eukaryotic host is a mould or a yeast. Thus the lower eukaryotic host can be a mould, e.g. belonging to the genera *Aspergillus* or  
30 *Trichoderma*, or a yeast, preferably belonging to the yeast genera *Saccharomyces*, *Kluyveromyces*, *Hansenula*, or *Pichia*. Preferably the fragments still contain the whole variable domain of these heavy chains.

The invention also provides methods to produce such heavy chain immunoglobulins or (functionalized) fragments thereof in which methods the framework or the CDRs of these heavy chains are modified by random or directed mutagenesis in such a way that the mutated heavy chain is optimized for secretion by the host microorganism  
5 into the fermentation medium.

Another embodiment of the invention is that CDRs can be grafted on these optimized frameworks (compare grafting of CDRs on human immunoglobulins as described by e.g. Jones *et al.*, Nature 321 (1986) 522). These CDRs can be obtained from common antibodies or they may originate from heavy chain immunoglobulins  
10 of *Camelidae*. The binding properties may be optimized by random or directed mutagenesis. Thus in a process according to the invention an antibody or (functionalized) fragment thereof derived from a heavy chain immunoglobulin of *Camelidae* can be produced which comprises a CDR different from the CDR belonging to the natural antibody ex *Camelidae* which is grafted on the framework  
15 of the variable domain of the heavy chain immunoglobulin ex *Camelidae*.

The invention also provides a method for the microbiological production of catalytic antibodies. These antibodies are preferably raised in *Camelidae* against transition state molecules following procedures similar to the one described by Lerner *et al.*, Science 252 (1991) 659-667. Using random or site-directed mutagenesis such  
20 catalytic antibodies or fragments thereof can be modified in such a way that the catalytic activity of these (functionalized) antibodies or fragments can be further improved.

For preparing modified heavy chain antibodies a process according to the invention is provided, in which the DNA sequence encodes a modified heavy chain immunoglobulin or a (functionalized) fragment thereof derived from *Camelidae* and being  
25 devoid of light chains, and is made by random or directed mutagenesis or both. Thus the resulting immunoglobulin or (functionalized) fragment thereof is modified such that

- it is better adapted for production by the host cell, or
- 30 - it is optimized for secretion by the lower eukaryotic host into the fermentation medium, or
- its binding properties ( $k_{on}$  and  $k_{off}$ ) are optimized, or

- its catalytic activity is improved, or
- it has acquired a metal chelating activity, or
- its physical stability is improved.

5 Another particular embodiment of the present invention relates to genes encoding fusion proteins consisting of both a heavy chain immunoglobulin from *Camelidae* or part thereof and a second protein or another polypeptide, e.g. an enzyme, in particular an oxido-reductase, and to expression products of such genes. By means of the heavy chain immunoglobulin (fragment) the protein or enzyme can be guided to a  
10 target thereby increasing the local efficiency of the protein or enzyme significantly. Thus according to this embodiment of the invention a process is provided, in which the functionalized antibody or fragment thereof comprises a fusion protein of both a heavy chain immunoglobulin from *Camelidae* or a fragment thereof and another polypeptide, e.g. an enzyme, preferably an oxido-reductase.

15

As a result of a process according to the invention known products may be produced, e.g. antibodies also produced by *Camelidae*, but many of the possible products will be new products, thus the invention also provides new products obtainable by a process according to the invention.

20 The products so produced can be used in compositions for various applications. Therefore, the invention also relates to compositions containing a product produced by a process according to the invention. This holds for both old products and new products.

- 30

**Detailed description of the invention**

The present invention relates to the production of antibodies or (functionalized) fragments thereof derived from heavy chain immunoglobulins of *Camelidae* by eukaryotes, more in particular by lower eukaryotes such as yeasts and fungi.

- 5 Therefore, mRNA encoding immunoglobulins of *Camelidae* was isolated and transcribed into cDNA according to the procedures described in the above given draft publication and not prior-published European patent application 92402326.0. In each case primers for the PCR reaction directed to the N-terminus of the  $V_H$  domain and PCR primers that either hybridize with the C-terminal regions of the
- 10  $V_H$  domain or with the short or large hinge regions as described in the above given draft publication, or with the C-terminal region of the  $C_H2$  or  $C_H3$  domains can be used. In this way structural genes can be obtained encoding the following fragments of heavy chain immunoglobulins of *Camelidae* (Table 2).

15

- 

25

According to procedures described in detail in the Examples these cDNAs can be integrated into expression vectors.

- Known expression vectors for *Saccharomyces*, *Kluyveromyces*, *Hansenula*, *Pichia* and *Aspergillus* can be used for incorporating a cDNA or a recombinant DNA according
- 30 to the invention. The resulting vectors contain the following sequences that are required for expression: (a) a constitutive, or preferably an inducible, promoter; (b) a leader or signal sequence; (c) one of the structural genes as described in Table 2

- and (d) a terminator. If the vector is an episomal vector, it preferably comprises an origin of replication as well as a selection marker, preferably a food grade selection marker, (EP-A-487159, UNILEVER / Leenhouts *et al.*). If the vector is an integration vector, then it preferably comprises sequences that ensure integration
- 5 and a selection marker in addition to the sequences required for expression of the structural gene encoding a form of the heavy chain immunoglobulin of *Camelidae* or derivatives thereof. The preferred sequences for integration are sequences encoding ribosomal DNA (WO 91/00920, 1991, UNILEVER / Giuseppin *et al.*) whereas the selection marker will be preferably a food grade marker.
- 10 For *Saccharomyces* the preferred inducible promoter is the GAL7 promoter (EP-A-0255153, UNILEVER / Fellinger *et al.*); for *Kluyveromyces* the preferred inducible promoter is the inulinase promoter (not yet published EP application 92203932.6, UNILEVER / Toschka & Verbakel, which is incorporated herein by reference); for *Hansenula* or *Pichia* the preferred inducible promoter is the methanol-oxidase
- 15 promoter (Sierkstra *et al.*, Current Genetics 19 (1991) 81-87) and for *Aspergillus* the preferred inducible promoter is the endo-xylanase promoter (not prior-published PCT application PCT/EP 92/02896, UNILEVER / Gouka *et al.*, now publicly available as WO-A-93/12237, which is incorporated herein by reference).
- To achieve efficient secretion of the heavy chain immunoglobulin or parts thereof
- 20 the leader (secretion) sequences of the following proteins are preferred: invertase and  $\alpha$ -factor for *Saccharomyces*, inulinase for *Kluyveromyces*, invertase for *Hansenula* or *Pichia* (Sierkstra *et al.*, 1991 *supra*) and either glucoamylase or xylanase for *Aspergillus* (not prior-published PCT application WO-A-93/12237, *supra*). As food-grade selection markers, genes encoding anabolic functions like the leucine2 and
- 25 tryptophan3 are preferred (Giuseppin *et al.* 1991, *supra*). The present invention describes the heterologous production of (functionalized) derivatives or fragments of immunoglobulins in a microorganism, which immunoglobulins in nature occur not as a composite of heavy chains and light chains, but only as a composite of heavy chains. Although the secretion mechanism of mammals and microorganisms is quite
- 30 similar, in details there are differences that are important for developing industrial processes.

To obtain frameworks of the heavy chain immunoglobulins, that are optimally secreted by lower eukaryotes, genes encoding several different heavy chains can be cloned into the coat protein of bacteriophages and subsequently the frameworks of these heavy chain immunoglobulins can be mutated using known PCR technology, e.g. Zhou *et al.*, (1991). Subsequently the mutated genes can be cloned in *Saccharomyces* and *Aspergillus* and the secretion of the mutated genes can be compared with the wild type genes. In this way frameworks optimized for secretion may be selected.

Alternatively these structural genes can be linked to the cell wall anchoring part of cell wall proteins, preferably GPI-linked cell wall proteins of lower eukaryotes, which result in the expression of a chimeric protein on the cell wall of these lower eukaryotes (not prior-published EP application 92202080.5, UNILEVER / Klis *et al.*, now publicly available as International (PCT) patent application WO-A-94/01567, which is incorporated herein by reference).

Both methods have the advantage that the binding parts of the immunoglobulins are well exposed to the surrounding of the cell, microorganism, or phage and therefore can bind antigens optimally. By changing the external conditions the binding rates and dissociation rates of this binding reaction can be influenced. Therefore, these systems are very suitable to select for mutated immunoglobulins that have different binding properties. The mutation of the immunoglobulins can either be obtained by random mutagenesis, or directed mutagenesis based on extensive molecular modelling and molecular dynamical studies.

mRNAs encoding heavy chains of immunoglobulins raised in *Camelidae* against transition state molecules (Lerner *et al.*, 1991 *supra*) can be obtained using standard techniques. The structural genes encoding various forms of immunoglobulins according to the invention as summarized in Table 2 can be cloned into the coat protein of bacteriophages or as fusion with the anchoring part of cell wall proteins and can be tested on the catalytic property. In this way immunoglobulins or parts thereof having catalytic properties can be determined and selected. Genes encoding these selected immunoglobulins or parts thereof can be mutated as described before and recloned in bacteriophages, but preferably cloned as chimeric cell wall bound catalysts in lower eukaryotes. By performing appropriate catalytic assays, catalytic

immunoglobulins or parts thereof with improved catalytic properties can be determined and selected using standard techniques.

An important application of antibodies, especially outside the pharmaceutical industry, will be chimeric proteins consisting of the binding part of antibodies and enzymes. In this way catalytic biomolecules can be designed that have two binding properties, one of the enzyme and the other of the antibody. This can result in enzymes that have superior activity. This can be illustrated with the following examples:

- a. If the substrate of the enzymic reaction is produced by an organism or an enzyme is recognized by the binding domain of the antibody, the local concentration of the substrate will be much higher than for enzymes lacking this binding domain and consequently the enzymic reaction will be improved. In fact this is a mimic of vectorial metabolism in cells (compare e.g. Mitchell, (1979) Science 206 1148-1159);
- b. If the substrate of the enzymic reaction is converted into a molecule that kills organisms, then the efficiency and specificity of killing can be increased significantly if the enzyme is equipped with an antibody binding domain that recognizes the target organism (e.g. compare Takahashi *et al.*, (1993) Science 259 1460-1463);

20

The invention will be illustrated by the following Examples without being limited thereto. In previously filed Unilever patent specifications several expression vectors were described, e.g. for the yeasts *S. cerevisiae*, *Kluyveromyces*, and *Hansenula*, and the mould *Aspergillus*. Examples of these publications are EP-A-0173378 (UNILEVER / Ledehoer *et al.*), EP-A-0255153, *supra*, and PCT applications WO-A-91/19782 (UNILEVER / van Gorcom *et al.*) and (not prior-published) WO-A-93/12237, *supra*. The genes encoding antibodies or (functionalized) fragments thereof according to the invention can be incorporated into the earlier described expression vectors or derivatives thereof using procedures well known to a skilled person in the art. All techniques used for the manipulation and analysis of nucleic acid materials were performed essentially as described in Sambrook *et al.* (1989)

30

(see also ref. 23 of the above given draft publication), except where indicated otherwise.

In the description of the Examples the following endonuclease restriction sites are used:

5	<i>Afl</i> II	C↓TTAAG	<i>Mlu</i> I	A↓CGCGT
	<i>Bsp</i> HI	T↓CATGA	<i>Nco</i> I	C↓CATGG
	<i>Bsp</i> HI	T↓CATGA	<i>Not</i> I	GC↓GGCCGC
	<i>Bst</i> EII	G↓GTNACC	<i>Nru</i> I	TCG↓CGA
	<i>Eag</i> I	C↓GGCCG	<i>Sal</i> I	G↓TCGAC
10	<i>Eco</i> RI	G↓AATTC	<i>Xho</i> I	C↓TCGAG
	<i>Hind</i> III	A↓AGCTT	<i>Bhs</i> I	GAAGAC(N) <sub>2</sub> ↓ CTTCTG(N') <sub>6</sub> ↓

#### 15 Example 1 Construction of cassettes encoding V<sub>H</sub> fragments originating from *Camelidae*.

For the production of V<sub>H</sub> fragments originating from *Camelidae*, the antibody gene fragments were isolated and cloned as described above in the draft publication. The thus obtained gene fragments encode the V<sub>H</sub> region, a short or a long hinge region and about 14 amino acids of the C<sub>H</sub>2 region. By using standard molecular biological techniques (e.g. PCR technology), the V<sub>H</sub> gene fragments could be subcloned and equipped at their 5'-ends with a gene fragment encoding the *pelB* signal sequence and at their 3'-ends with a gene fragment encoding the Flag tail (13 amino acids). Three of these clones were named pB3, pB9 and pB24 and were deposited at the Centraal Bureau voor Schimmelcultures, Baarn on 20 April 1993 with deposition numbers: CBS 270.93, CBS 271.93 and CBS 272.93, respectively. The DNA and amino acid sequences of the *Camelidae*-V<sub>H</sub> fragments followed by the Flag sequence are presented in Figure 5(A-C); see SEQ. ID. NO: 32-37.

#### 1.1 Construction of pUR4421

30 For the construction of yeast expression plasmids encoding the V<sub>H</sub> fragments preceded by the invertase (=SUC2) signal sequence, the α-mating factor prepro-

sequence, or the inulinase signal sequence and followed by either nothing, or a Myc tail or Flag tail, the constructs described below can be prepared.

The multiple cloning site of plasmid pEMBL9 (Denthe *et al.*, 1983) (ranging from the *EcoRI* to the *HindIII* site) was replaced by a synthetic DNA fragment having the  
5 nucleotide sequence as indicated in Figure 6; see SEQ. ID. NO: 38-41. The 5'-part of this nucleotide sequence comprises an *EagI* site, the first 4 codons of the *Camelidae* V<sub>H</sub> gene fragment and a *XhoI* site coinciding with codons 5 and 6. The 3'-part comprises the last 5 codons of the *Camelidae* V<sub>H</sub> gene (encoding VTVSS; see SEQ. ID. NO: 47) part of which coincides partially with a *BstEII* site), eleven codons  
10 of the Myc tail, and an *EcoRI* site. The *EcoRI* site, originally present in pEMBL9, is not functional any more, because the 5'- end of the nucleotide sequence contains AATTT instead of AATTC, indicated in Figure 6 as "(*EcoRI*)". The resulting plasmid is called pUR4421.

### 15 1.2 Constructs with Flag tail.

After digesting the plasmid pB3 with *XhoI* and *EcoRI*, a DNA fragment of approximately 425 bp was isolated from agarose gel. This fragment codes for a truncated V<sub>H</sub>-Flag fragment, missing the first 5 amino acids of the *Camelidae* V<sub>H</sub>.  
The obtained fragment can be cloned into pUR4421. To this end plasmid pUR4421  
20 can be digested with *XhoI* and *EcoRI*, after which the about 4 kb vector fragment can be isolated from an agarose gel. Ligation with the about 425 bp fragment will result in plasmid pUR4421-03F.

### 1.3 Constructs with Myc tail.

25 After digesting the plasmid pB3 with *XhoI* and *BstEII*, a DNA fragment of approximately 365 bp was isolated from agarose gel. This fragment codes for a truncated V<sub>H</sub> fragment, missing both the first 4 (QVKL; see SEQ. ID. NO: 46) and the last 5 (VTVSS; see SEQ. ID. NO: 47) amino acids of the *Camelidae* V<sub>H</sub> fragment.

30 The obtained fragment was cloned into pUR4421. To this end plasmid pUR4421 was digested with *XhoI* and *BstEII*, after which the about 4 kb vector fragment was isolated from an agarose gel. Ligation with the about 365 bp fragment resulted in

plasmid pUR4421-03M, in which the gene encoding the  $V_H$  fragment is reconstituted.

#### 1.4 Constructs encoding $V_H$ only.

- 5 Upon digesting pUR4421-03M or pUR4421-03F with *Bst*EII and *Hind*III, the vector fragments of about 4.4 kb can be isolated from agarose gel and religated in the presence of a synthetic linker peptide having the following sequence:

10  $\begin{array}{ccc} \text{BstEII} & & \text{HindIII} \\ \text{GTCACCGTCTCCTCATAATGA} & & \\ \hline & \text{GCAGAGGAGTATTACTTCGA} & \end{array}$  (see SEQ. ID. NO: 48-49).

In the thus obtained plasmid, pUR4421-03, the Myc tail or Flag tail sequences are removed and the  $V_H$  gene fragment is directly followed by a stop codon.

#### 1.5 Other constructs.

- 15 After isolating the gene fragments encoding  $V_H$ -hinge- $C_H2$  fragments as described above in the draft publication, or encoding the intact heavy chain immunoglobulin, it is possible, e.g. by using PCR technology, to introduce an appropriate restriction enzyme recognition site (e.g. *Eco*RI or *Hind*III) downstream of the hinge region, downstream of the  $C_H2$  region, or downstream of the total gene. Upon isolating a  
20 *Xho*I-*Eco*RI or *Xho*I-*Hind*III fragment encoding the  $V_H$  fragment with a C-terminal extension, the fragment can be cloned into pUR4421 digested with the same restriction enzymes.

- In analogy with the construction of pUR4421-03, a number of other constructs can be produced encoding functionalized heavy chain fragments in which a second  
25 polypeptide is fused to the C-terminal part of the  $V_H$  fragment. Optionally, the  $V_H$  fragment and the second polypeptide, e.g. an enzyme, might be connected to each other by a peptide linker.

- To this end either the *Bst*EII-*Hind*III fragment or the *Bst*EII-*Eco*RI fragment of either pUR4421-03F or pUR4421-03M has to be replaced by another *Bst*EII-*Hind*III  
30 or *Bst*EII-*Eco*RI fragment. The latter new fragment should code for the last amino acids (VTVSS, see SEQ.ID. NO: 47) of the  $V_H$  fragment, optionally for a linker peptide, and for the polypeptide of interest e.g. an enzyme. Obviously, the introduction of the DNA fragment should result in an in frame fusion between the

V<sub>H</sub> gene fragment and the other DNA sequence encoding the polypeptide of interest.

Alternatively, it is possible to replace the *EagI-XhoI* fragment of pUR4421-03 with  
5 another DNA fragment, coding for a polypeptide of interest, optionally for a peptide linker, and for the first 4 (QVKL, see SEQ.ID. NO: 46) amino acids of the V<sub>H</sub> fragment, resulting in an in frame fusion with the remaining part of the V<sub>H</sub> fragment. In this way, it is possible to construct genes encoding functionalized V<sub>H</sub> fragments in which the second polypeptide is fused at the N-terminal part of the V<sub>H</sub>  
10 fragment, optionally via a peptide linker.

Obviously, it is also possible to construct genes encoding functionalized V<sub>H</sub> fragments having a polypeptide fused to the N-terminal as well as fused to the C-terminal end, by combining the above described construction routes.

The polypeptides used to functionalize the V<sub>H</sub> fragments might be small, like the  
15 Myc and the Flag tails, or intact enzymes, like glucose oxidase, or both.

From all the above described constructs, derived from pUR4421, an appropriate *EagI-HindIII* fragment, encoding the functionalized V<sub>H</sub> fragment, can be isolated and cloned into a number of different expression plasmids. Several are exemplified  
20 in more detail in the following Examples. Although only the V<sub>H</sub> fragments are exemplified, similar constructs can be prepared for the production of larger heavy chain fragments (e.g. V<sub>H</sub>-hinge or V<sub>H</sub>-hinge-C<sub>H</sub>2) or intact heavy chains. The *EagI* site is introduced before the first codon of the V<sub>H</sub> fragment, facilitating an in frame fusion with different yeast signal sequences.

25 In particular cases, where additional *EagI* and/or *HindIII* sites are present in the cloned fragments, it is necessary to perform partial digestions with one or both restriction enzymes.

Although the above and following constructions only consider the V<sub>H</sub> fragment  
30 cloned in pB3, a comparable construction route can be used for the construction of expression plasmids for the production of V<sub>H</sub> fragments like V<sub>H</sub>-09 and V<sub>H</sub>-24, or other V<sub>H</sub> fragments.

**Example 2      Construction of *S. cerevisiae* episomal expression plasmids for  
Camelidae V<sub>H</sub>.**

For the secretion of recombinant protein from *S. cerevisiae* it is worthwhile to test in parallel the two most frequently applied homologous signal sequences, the SUC2

5 invertase signal sequence and the prepro- $\alpha$  mating factor sequence.

The episomal plasmid pSY1 and pSY16 (Harmsen *et al.*, 1993) contain expression cassettes for the  $\alpha$ -galactosidase gene. Both plasmids contain the GAL7 promoter and PGK terminator sequences. pSY1 contains the invertase (SUC2) signal sequence and pSY16 contains a slightly modified (Harmsen *et al.*, 1993) prepro- $\alpha$ -  
10 mating factor signal sequence.

Both plasmids, pSY1 and pSY16 can be digested with *EagI* and *HindIII*, the about 6500 bp long vector backbone of both plasmids can be isolated and subsequently ligated with the *EagI/HindIII* fragments from pUR4421-03F (~465 bp), pUR4421-03M (~455 bp) or pUR4421-03 (~405 bp) (See above).

15 This results in a series of 6 different episomal plasmids for expression in *S. cerevisiae*, containing behind the SUC2- and the  $\alpha$  mating factor prepro-sequence the V<sub>H</sub>-Flag coding sequence (designated pUR4423F and pUR4426F), the V<sub>H</sub>-Myc coding sequence (designated pUR4423M and pUR4426M) or the coding sequence of V<sub>H</sub> followed by a stop codon (designated pUR4423, Figure 7 and pUR4426,  
20 Figure 8).

Obviously, it is possible to use promoter systems different from the inducible GAL7 promoter, e.g. the constitutive GAPDH promoter.

**2.1      Production of V<sub>H</sub>-03-myc and V<sub>H</sub>-24-myc.**

25 After introducing the expression plasmids pUR4423M (coding for V<sub>H</sub>-03-myc, preceded by the SUC2-signal sequence) and pUR4425M (coding for V<sub>H</sub>-24-myc, preceded by the SUC2-signal sequence) into *S. cerevisiae* via electroporation, transformants were selected from minimal medium agar plates (comprising 0.7 % yeast nitrogen base, 2 % glucose and 2 % agar, supplemented with the essential  
30 amino acids and bases).

For the production of antibody fragments the transformants were grown overnight in selective minimal medium (comprising 0.7 % yeast nitrogen base, 2 % glucose,

supplemented with the essential amino acids and bases) and subsequently diluted ten times in YPGal medium (comprising 1 % yeast extract, 2 % bacto pepton and 5 % galactose). After 24 and 48 hours of growth, samples were taken for Western blot analysis (Figure 21). For the immuno detection of the produced V<sub>II</sub>-myc fragments monoclonal anti-myc antibodies were used.

In essentially the same way comparable results were obtained with a yeast transformed with pUR4424M containing a DNA sequence encoding the V<sub>II</sub>-09-myc protein.

**Example 3** Construction of *S. cerevisiae* multicopy integration vectors for the expression of *Camelidae* V<sub>II</sub>.

To combine the benefits of high copy number and mitotically stable expression, the concept of a multicopy integration system into the rDNA locus of lower eukaryotes has already been successfully proven (Giuseppin *et al. supra*).

One of these vectors is pUR2778, a derivative of pUR2774 (Giuseppin *et al. supra*) from which the pol1-S.O. reporter gene sequence was removed (Figure 9).

This integrating plasmid, pUR2778, can be used for integration of *Camelidae* V<sub>H</sub> coding sequences, hence the vector can be digested with *Sac*I and *Hind*III after which the ~7.3 kb vector fragment can be isolated.

From the in example 2 described pUR4423 or pUR4426 types of plasmids, *SacI*-*HindIII* fragments can be isolated encoding a V<sub>H</sub> fragment preceded by a signal sequence (SUC2 or  $\alpha$  mating factor prepro) and followed by nothing or a Myc or Flag tail.

Ligation of these *SacI-HindIII* fragments with the ~7.3 kb vector fragment will result in integration plasmids, encoding the (functionalized) V<sub>H</sub> fragments under the regulation of the strong and inducible GAL7 promoter.

In this way the following expression plasmids were obtained:

pUR4429	P <sub>gal7</sub> - SUC2 sig.seq. - V <sub>II</sub> -03
pUR4429F	P <sub>gal7</sub> - SUC2 sig.seq. - V <sub>II</sub> -03 - Flag tail
pUR4429M	P <sub>gal7</sub> - SUC2 sig.seq. - V <sub>II</sub> -03 - Myc tail
pUR4430	P <sub>gal7</sub> - $\alpha$ mat.fac. prepro. - V <sub>II</sub> -03
5 pUR4430F	P <sub>gal7</sub> - $\alpha$ mat.fac. prepro. - V <sub>II</sub> -03 - Flag tail
pUR4430M	P <sub>gal7</sub> - $\alpha$ mat.fac. prepro. - V <sub>II</sub> -03 - Myc tail

For schematic drawings see Figure 10 for pUR4429 and Figure 11 for pUR4430.

Obviously, comparable constructs can be prepared for other heavy chain antibodies  
 10 or fragments thereof.

As mentioned before, different promoters might be used, for example, the constitutive GAPDH promoter.

#### 15 **Example 4 Construction of expression plasmids for the production of (functionalized) V<sub>II</sub> fragments from *Camelidae* by *Kluyveromyces***

##### **4.1. Construction of *Kluyveromyces lactis* episomal expression plasmids *Camelidae*.**

Yeast strains of the genus *Kluyveromyces* have been used for the production of enzymes, such as  $\beta$ -galactosidase for many years, and the growth of the strains has  
 20 been extensively studied. *Kluyveromyces lactis* is well known for the ability to utilize a large variety of compounds as carbon and energy sources for growth. Since these strains are able to grow at high temperatures and exhibit high growth rates, they are promising hosts for industrial production of heterologous proteins (Hollenberg, C. *et al.*, EP-A-0096430, GIST-BROCADES N.V., 1983).

25 The plasmids pUR2427 and pUR2428 are pTZ19R derivatives with the promoter and the DNA sequence encoding either the signal peptide (=pre-sequence) (in pUR2428), or the natural prepro-sequence (in pUR2427), of inulinase (inu) from *Kluyveromyces marxianus*. Both plasmids contain a unique *Bsp*MI site suitable to create a perfect joint with *Eag*I or *Not*I digested DNA-fragments (not yet published  
 30 European patent application 92203932.6, *supra*). In both plasmids a unique *Hind*III site is located a bit further downstream of the *Bsp*MI-site, so that *Eag*I-*Hind*III cut DNA-fragments encoding V<sub>II</sub> from *Camelidae* either solely or with Myc- or Flag- tail

can be easily ligated into *Bsp*MI-*Hind*III digested pUR2427 or pUR2428. Thereby a set of six plasmids can be created containing the promoter and secretion signals of the *Kluyveromyces marxianus* inulinase gene, joint in frame to *Camelidae* Vh encoding sequences, all on a *Eco*RI-*Hind*III restriction fragment:

- 5 pUR4445 P<sub>inu</sub> - Inu prepro seq. - V<sub>II</sub> - 03
- pUR4445M P<sub>inu</sub> - Inu prepro seq. - V<sub>II</sub> - 03 - Myc
- pUR4445F P<sub>inu</sub> - Inu prepro seq. - V<sub>II</sub> - 03 - Flag
- pUR4446 P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03
- pUR4446M P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03 - Myc
- 10 pUR4446F P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03 - Flag .

Maps of pUR4445 and pUR4446 are shown in Figure 12 and Figure 13.

- The *Eco*RI-*Hind*III fragments of these plasmids can be ligated into the expression vector pSK1 (not yet published European patent application 92203932.6, *supra*),
- 15 from which the  $\alpha$ -galactosidase expression cassette including the *GAL7*-promoter is removed with a *Eco*RI(partial) and *Hind*III digestion. The resulting plasmids can then be transformed for example in *K. lactis* strain MSK110 (a, *uraA*, *trp1::URA3*), as they contain the *trp1* marker and the pKD1 episomal plasmid sequences:

- pUR4447 P<sub>inu</sub> - Inu prepro seq. - V<sub>H</sub> - 03
- 20 pUR4447M P<sub>inu</sub> - Inu prepro seq. - V<sub>H</sub> - 03 - Myc
- pUR4447F P<sub>inu</sub> - Inu prepro seq. - V<sub>H</sub> - 03 - Flag
- pUR4448 P<sub>inu</sub> - Inu pre seq. - V<sub>H</sub> - 03
- pUR4448M P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03 - Myc
- pUR4448F P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03 - Flag .
- 25 A map of pUR4447 is shown in Figure 14.

Transformation can be performed by standard techniques such as the methods of Beggs (1978) or electroporation, using 0.67% Yeast Nitrogen Base (without amino acids) and 2% glucose as the selection medium for transformants.

#### 4.2. Construction of *Kluyveromyces lactis* multicopy integration vectors.

Alternatively, since all tailed and non-tailed versions of the V<sub>H</sub> fragments, joined to the inulinase promoter and secretion signals, are located on *EcoRI-HindIII* fragments, the rDNA multicopy integration plasmid pMIRKGAL-T $\Delta$ 1 (Bergkamp *et al.*, 1992) can be used in a similar way as the pSK1 plasmid. In order to replace the  $\alpha$ -gal expression cassette present in this plasmid, by a antibody fragment cassette, these plasmids have to be digested with *EcoRI*(partial) and *HindIII*. After isolating the vector fragments, they can be ligated with the about 1.2 kb *EcoRI-HindIII* fragments which can be obtained from the plasmids described in example 4.1. The resulting plasmids can be linearized with *SacII* and transformed to MSK110, resulting in *K. lactis* strains with potentially high and stable expression of single chain V<sub>H</sub> fragments.

pUR4449	P <sub>inu</sub> - Inu prepro seq. - V <sub>H</sub> - 03
pUR4449M	P <sub>inu</sub> - Inu prepro seq. - V <sub>H</sub> - 03 - Myc
15 pUR4449F	P <sub>inu</sub> - Inu prepro seq. - V <sub>H</sub> - 03 - Flag
pUR4450	P <sub>inu</sub> - Inu pre seq. - V <sub>H</sub> - 03
pUR4450M	P <sub>inu</sub> - Inu pre seq. - V <sub>H</sub> - 03 - Myc
pUR4450F	P <sub>inu</sub> - Inu pre seq. - V <sub>H</sub> - 03 - Flag .

#### 20 4.3. Construction of *Kluyveromyces marxianus* episomal plasmids.

*Kluyveromyces marxianus* is a yeast which is perhaps even more attractive than *K. lactis* for industrial biotechnology, due to its short generation time on glucose (about 45 minutes) and its ability to grow on a wide range of substrates, and its growth at elevated temperatures (Rouwenhorst *et al.*, 1988).

25 The shuttle vector pUR2434, containing the leu2 marker and the pKD1 plasmid sequences (not yet published European patent application 92203932.6, *supra*), located on a pUC19 based vector, can be cut with *EcoRI*(partial) and *HindIII* to remove the  $\alpha$ -galactosidase expression cassette. In this vector the *EcoRI-HindIII* fragments containing the V<sub>H</sub> expression cassettes as described in example 4.1, can be

30 ligated. The resulting plasmids can then be transformed into KMS3, the neat leu2-auxotroph CBS6556 *K. marxianus* strain (Bergkamp, 1993) using the method of Meilhoc *et al.* (1990).

- pUR4451      P<sub>inu</sub> - Inu prepro seq. - V<sub>II</sub> - 03  
 pUR4451M    P<sub>inu</sub> - Inu prepro seq. - V<sub>II</sub> - 03 - Myc  
 pUR4451F    P<sub>inu</sub> - Inu prepro seq. - V<sub>II</sub> - 03 - Flag  
 pUR4452      P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03  
 5 pUR4452M    P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03 - Myc  
 pUR4452F    P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03 - Flag .

A map of pUR4451 is shown in Figure 15.

#### 4.4 Construction of *Kluyveromyces marxianus* multicopy integration vectors.

- 10 For high and stable expression in *Kluyveromyces marxianus*, the multicopy integration system as described by Bergkamp (1993), can be used. The following cloning route, based on the route for constructing pMIRKM-GAL5 (Bergkamp, 1993), results in suitable expression vectors for production of Vh fragments from *Camelidae*. The *EcoRI-NheI*(Klenow filled) fragments of pUR4447,-M,-F and pUR4448,-M,-F  
 15 containing the Vh fragment expression cassettes as described in example 4.1, can be isolated and ligated in *EcoRI-EcoRV* digested pIC-20H. From the plasmids obtained in this way, and which are equivalents of the pIC- $\alpha$ gal plasmid, the *BamHI-NruI* fragment can be isolated and ligated with *BamHI-SmaI* digested pMIRKM4. The result of this will be expression vectors which are equivalent to pMIRKM-GAL5,  
 20 and contain a tailed or non-tailed Vh fragment from camel under control of inulinase promoter and secretion signals, in a vector which also contains the *K. marxianus* LEU2-gene with defective promoter, and *K. marxianus* rDNA sequences for targeted integration into the genome. These vectors can be used to transform for example KMS3.

- 25 pUR4453      P<sub>inu</sub> - Inu prepro seq. - V<sub>II</sub> - 03  
 pUR4453M    P<sub>inu</sub> - Inu prepro seq. - V<sub>II</sub> - 03 - Myc  
 pUR4453M    P<sub>inu</sub> - Inu prepro seq. - V<sub>II</sub> - 03 - Flag  
 pUR4454      P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03  
 pUR4454M    P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03 - Myc  
 30 pUR4454F    P<sub>inu</sub> - Inu pre seq. - V<sub>II</sub> - 03 - Flag .

A map of pUR4453 is shown in Figure 16.

**Example 5. Construction of *Hansenula polymorpha* integrating vectors for the expression of (functionalized)  $V_{H1}$  fragments from *Camelidae*.**

In search for productive systems able to carry out authentic posttranscriptional processing and overcoming the limitation of higher eukaryotic expression systems, such as high costs, low productivity and the need for stringent control procedures for the detection of contaminating agents could be overcome by the methylotrophic yeast *H. polymorpha*. This strain is able to grow on methanol as its sole carbon and energy source, so the presence of methanol in the growth medium rapidly induces the enzymes of the methanol pathway, such as the key enzymes methanol oxidase (MOX) and dihydroxyacetone synthase (DHAS).

While experiments to express foreign genetic information from an episomal plasmid resulted in a low plasmid stability, chromosomal integration is the method of choice (Sierkstra *et al.*, 1991). By utilizing the DNA of the *mox* gene as integration locus the latter were able to express and secrete  $\alpha$ -galactosidase regulated by *mox* promoter and -terminator. Here, the *S. cerevisiae* SUC2 signal sequence was proven to be efficiently functional for secretion.

The same approach can be used for expression and secretion of *Camelidae*  $V_H$  antibody fragments. Plasmids analogous to pUR3515 (without an origin of replication functional in yeast) and pUR3517 (containing the HARS2 sequence as origin of replication) can be used as expression vectors (Sierkstra *et al.*, 1991). As a starting vector pUR3501 can be used (Sierkstra *et al.*, 1991) in which by means of site directed mutagenesis (e.g. via PCR technology), an *EagI* restriction site is introduced at the junction between the invertase (=SUC2) signal sequence and the  $\alpha$ -galactosidase. From the resulting plasmid, pUR3501*Eag*, it is possible to replace the *EagI*-*HindIII* fragment comprising the  $\alpha$ -galactosidase gene by an *EagI*-*HindIII* fragment encoding a (functionalized) antibody fragment, obtained as described in example 1. In case of using the *EagI*-*HindIII* fragments of the pUR4421-03 series (example 1), this would result in plasmids pUR4437 (Figure 17), pUR4437M and pUR4437F. In these plasmids the nucleotide sequence encoding the (functionalized)  $V_{H1}$  is preceded by a nucleotide sequence encoding the invertase signal sequence and the *mox* promoter sequence. The obtained plasmids can be digested with *Bam*HI and *Hind*III and after filling in the sticky ends with Klenow polymerase, the about

2.6 kb fragments can be ligated into plasmid pUR3511 which was digested with *Sma*I (Sierkstra *et al.*, 1991). In this way the terminator sequence of the *mox* gene can be fused downstream of the  $V_{II}$  encoding sequences. From the thus obtained plasmids, pUR4438 (Figure 17) *Eco*RI-*Hind*III fragments of about 3 kb can be isolated, containing the *mox* promoter, the invertase signal sequence, the (functionalized)  $V_{II}$  fragment and the *mox* transcription terminator. Subsequently these fragments can be cloned into plasmid pUR3513 (no yeast origin of replication) or in pUR3514 (HARS origin of replication) as described by Sierkstra *et al.* (1991), resulting in two sets of plasmids:

10

pUR4439	$P_{mox}$ - SUC2 sig. seq. - $V_{II}$ - <i>mox</i> term. -- no origin
pUR4439M	$P_{mox}$ - SUC2 sig. seq. - $V_{II}$ - <i>mox</i> term. -- no origin
pUR4439F	$P_{mox}$ - SUC2 sig. seq. - $V_{II}$ - <i>mox</i> term. -- no origin
pUR4440	$P_{mox}$ - SUC2 sig. seq. - $V_{II}$ - <i>mox</i> term. -- HARS origin
15 pUR4440M	$P_{mox}$ - SUC2 sig. seq. - $V_{II}$ - <i>mox</i> term. -- HARS origin
pUR4440F	$P_{mox}$ - SUC2 sig. seq. - $V_{II}$ - <i>mox</i> term. -- HARS origin .

Maps of pUR4439 and pUR4440 are shown in Figure 18.

Essentially the same can be done with other *Eag*I-*Hind*III fragment, obtained as described in example 1.

20

The newly obtained plasmids can be transformed by electroporation of *H. polymorpha* A16 (CBS4732, *leu*-) and can be selected by growing on selective medium containing 0.68% YNB and 2% glucose. Induction medium should contain 0.5% methanol instead of the glucose.

25

#### Example 6 Construction *Aspergillus niger* var. *awamori* integration vectors for the production of $V_{II}$ fragments from *Camelidae*.

The multiple cloning site of plasmid pEMBL9 (ranging from the *Eco*RI to the *Hind*III site) was replaced by a synthetic DNA fragment having the nucleotide sequence as indicated in Figure 19; see SEQ. ID. NO: 42-45. The 5'- part of the nucleotide sequence contains a *Nru*I restriction site followed by the first codons of the *Camelidae*  $V_{II}$  gene fragment and a *Xho*I restriction site. The 3'-part encodes for

30

a *Bst*EII restriction site, the last codons of the *Camelidae* V<sub>H</sub> gene, eleven codons of the Myc tail and finally a *Eco*RI and a *Afl*II site. The resulting plasmid is pUR4432.

After digesting plasmid pB3 with *Xho*I and *Eco*RI, a DNA fragment of approximately 425 bp can be isolated from agarose gel. This fragment codes for a truncated V<sub>H</sub>-Flag fragment, missing the first 5 amino acids of the *Camelidae* V<sub>H</sub>. The obtained fragment can be cloned into pUR4432. To this end plasmid pUR4432 can be digested with *Xho*I and *Eco*RI, after which the about 4 kb vector fragment was isolated from an agarose gel. Ligation with the about 425 bp fragment resulted in plasmid pUR4433F.

After digesting the plasmids pB3 with *Xho*I and *Bst*EII, a DNA fragment of approximately 365 bp was isolated from agarose gel. This fragment codes for a truncated V<sub>H</sub> fragments, missing the first and last 5 amino acids of the *Camelidae* V<sub>H</sub>. The obtained fragment was cloned into pUR4432. To this end plasmids pUR4432 can be digested with *Xho*I and *Bst*EII, after which the about 4 kb vector fragment was isolated from an agarose gel. Ligation with the about 365 bp fragments resulted in plasmids pUR4433M. In a similar way the *Xho*I-*Bst*EII fragments of pB9 and pB24 were cloned into the pUR4432 vector fragment, resulting in pUR4434M and pUR4435M, respectively.

Upon digesting pUR4433M or pUR4433F with *Bst*EII and *Hind*III, the vector fragments of about 4.4 kb can be isolated from agarose gel and religated in the presence of a synthetic linker peptide having the following sequence:

25 

<i>Bst</i> EII	<i>Afl</i> II	<i>Hind</i> III	
<u>GTCACCGTCTCCTCATAATGATCTTAAGGTGATA</u>			
	GCAGAGGAGTATTACTAGAATTCCACTATTTCGA		(see SEQ. ID. NO: 50-51).

In the thus obtained plasmid, pUR4433, the Myc tail or Flag tail sequences are removed and the V<sub>H</sub> gene fragment is directly followed by a stop codon.

30 Analogous as described in example 1.5, it is possible to clone nucleotide sequences encoding longer fragments of the heavy chain immunoglobulins into pUR4432 or to replace the *Bst*EII-*Afl*II fragments of the above mentioned plasmids pUR4433,

pUR4433F or pUR4433M with other *BstEII-AflII* fragments, resulting in frame fusions encoding functionalized  $V_H$  fragments, having a C-terminal extension.

Upon replacing the *NruI-XhoI* fragments of pUR4433, pUR4433F or pUR4433M, in frame fusions can be constructed encoding functionalized  $V_H$  fragments, having an  
5 N-terminal extension.

In the above described constructs an *NruI* site was introduced before the first codon of the (functionalized)  $V_H$  fragment, facilitating an in frame fusion with the precursor-sequence of xylanase, see (not prior-published) WO-A-93/12237, *supra*.

For the construction of *Aspergillus* expression plasmids, from the plasmids

10 pUR4433F, pUR4433M and pUR4433, respectively, an about 455, 445 and 405 bp *NruI-AflII* fragment has to be isolated encoding the  $V_H$  fragment with a Flag, a Myc or no tail.

Plasmid pAW14B was the starting vector for construction of a series of expression  
15 plasmids containing the *exlA* expression signals and the genes coding for (functionalized)  $V_H$  fragments of *Camelidae* heavy chain antibodies. The plasmid comprises an *Aspergillus niger* var. *awamori* chromosomal 5 kb *SalI* fragment on which the 0.7 kb *exlA* gene is located, together with 2.5 kb of 5'-flanking sequences and 2.0 kb of 3'-flanking sequences (see Figure 20 and (not prior-published) WO-A-  
20 93/12237, *supra*).

Starting from pAW14B, pAW14B-10 was constructed by removing the *EcoRI* site originating from the pUC19 polylinker, and introducing a *NotI* site. This was achieved by digesting plasmid pAW14B with *EcoRI* and after dephosphorylation the linear 7.9 kb *EcoRI* fragment was isolated. The fragment was religated in the  
25 presence of the "*EcoRI*"-*NotI* linker:

5'- AATTGCGGCCGC -3'

(see SEQ. ID. NO: 52).

Subsequently the *AflII* site, located downstream of the *exlA* terminator was removed by partially cleaving plasmid pAW14B-10 and religating the isolated, linearized plasmid after filling in the sticky ends, resulting in plasmid  
30 pAW14B-11.

Finally, pAW14B-12 was constructed using pAW14B-11 as starting material. After digestion of pAW14B-11 with *AflII* (overlapping with the *exlA* stop codon) and *BglII*

(located in the *exl* promoter) the ~2.4 kb *Afl*III-*Bgl*II fragment, containing part of the *exlA* promoter and the *exlA* gene was isolated as well as the ~5.5 kb *Afl*III-*Bgl*II vector fragment. After partial digestion of this ~2.4 kb fragment with *Bsp*HI (located in the *exlA* promoter and at the *exlA* start codon) an about 1.8 kb *Bgl*II-*Bsp*HI *exlA* promoter fragment (up to the ATG initiation codon) was isolated and  
 5 ligated with the about 5.5 kb *Afl*III-*Bgl*II vector fragment of pAW14B-11 in the presence of the following adaptor:

(BspHI) BbsI      AflIII  
CATGCAGTCTTCGGGC  
 10                    GTCAGAAGCCGAATT

(see SEQ. ID. NO: 53-54) .

For the construction of the  $V_{H1}$  expression plasmids, pAW14B-11 can be partially digested with *Nru*I and digested with *Afl*III, after which the ~ 7 kb vector fragment can be isolated from agarose gel and contains the xylanase promoter, the DNA sequence encoding the xylanase signal sequence and the xylanase terminator. Upon  
 15 ligation of the *Nru*I-*Afl*III fragments of pUR4433M, pUR4434M and pUR4435M with the pAW14B-11 vector, plasmids pUR4436M, pUR4437M and pUR4438M were obtained, respectively. In these plasmids the *Camelidae*  $V_H$  polypeptides are preceded by the 27 amino acid long precursor sequence of xylanase and followed by the myc-tail (of 11 amino acids; see Examples 1.3 en 2, Figures 6 and 19, and  
 20 SEQ.ID. NO: 41 = 45).

In a similar way plasmids can be constructed encoding the  $V_H$  fragments followed by the FLAG-tail or without a tail.

After introducing the *amdS* and *pyrG* selection markers into the unique *Not*I site of pUR4436M, pUR4437M and pUR4438M using conventional techniques, e.g. as  
 25 described in Examples 2 and 3 of (not prior-published) WO-A-93/12237, *supra*, the plasmids were transferred to *Aspergillus*.

Production of the Camel  $V_{H1}$  fragments by the selected transformants was achieved by growing the strains in inducing medium essentially as described in example 2.2 of (not prior-published) WO-A-93/12237, *supra*. Western blot analysis of the culture  
 30 medium was performed as described in Example 2.1 above and revealed the presence of the antibody fragments.

Obviously, expression vectors can be constructed in which different promoter systems, e.g. glucoamylase promoter, and/or different signal sequences, e.g. glucoamylase or glucose oxidase signal sequences, are used.

#### 5 Example 7 Production of glucose oxidase - V<sub>II</sub> fusion proteins

Glucose oxidase catalyses the oxidation of D-glucose to D-gluconate under the release of hydrogen peroxide. Glucose oxidase genes (*gox*) from *Aspergillus niger* have been cloned (Frederick *et al.* (1990) J. Biol. Chem. 265 3793, Kriechbaum *et al.*, 1989) and the nucleotide sequences are available from the EMBL data bank  
10 under accession numbers J05242 and X16061. The nucleotide sequence of the latter is used as a basis for the following construction route.

Upon cloning the *gox* gene from *A. niger* it is possible, by applying PCR technology, to introduce convenient restriction sites.

To introduce a *Bsp*HI restriction site, overlapping with the ATG initiation codon,  
15 the sequence ATC ATG CAG can be changed to ATC ATG AGG. In the same experiment an *Eco*RI restriction site can be introduced which is located upstream of the *Bsp*HI site. This can be achieved by using the following PCR primer:

*Eco*RI                      *Bsp*HI

5'-TCACTGAATTCGGGATC ATG AGG ACT CTC CTT GTG AGC TCG CTT-3'

20 (see SEQ. ID. NO: 55).

A second PCR primer, having the following sequence can be used:

*Afl*III                      *Bbs*I                      *Sal*I

5'-ATGTCACAAAGCTTAAGCAGCAGACA GTC GAC CGT GCG GCC GGA GAC-3'

*Hind*III

25 (see SEQ. ID. NO: 56)

in the same PCR experiment, in order to introduce a *Bbs*I site, a *Afl*III site and a *Hind*III site, downstream of the unique *Sal*I site present in the glucose oxidase gene. After digesting the DNA obtained from this PCR experiment with *Eco*RI and *Hind*III, an *Eco*RI - *Hind*III fragment of about 160 bp can be isolated and cloned  
30 into pEMBL9, which was digested with the same enzymes, resulting in plasmid pGOX1.

From pGOX1 an about 140 bp *Bsp*HI - *Afl*III fragment can be isolated and introduced into the 7.2 kb *Bbs*I-*Afl*III vector fragment of pAW14B-12, resulting in

pAW14B-GOX. In this plasmid, the 5'- part of the *gox* gene, encoding the first 43 amino acids, is fused in frame with the ATG initiation codon of the *exlA* gene.

In a second PCR experiment, a *Mlu*I restriction site can be introduced near the 3'-end of the *gox* by changing the sequence TAT GCT TCC to TAC GCG TCC. In the same experiment a *Hind*III site can be introduced downstream of the *Mlu*I site. As a second primer an oligo nucleotide should be used hybridizing upstream of the *Sal*I site. After digesting the DNA obtained from this PCR experiment with *Sal*I and *Hind*III, an *Sal*I - *Hind*III fragment of about 1.7 kb can be isolated and cloned into pEMBL9, which was digested with the same enzymes, resulting in plasmid pGOX2. Upon digesting pGOX2 with *Mlu*I and *Hind*III, an about 5.7 kb vector fragment can be isolated.

From the plasmids pUR4433, pUR4433F, pUR4433M and the like, *XhoI-HindIII* fragments can be isolated, encoding the truncated *Camelidae* V<sub>II</sub> fragment with or without a tail sequence, and missing the first 4-6 N-terminal amino acids (see Example 1). These fragments can be ligated into the 5.7 kb pGOX2 vector fragment by using *MluI-XhoI* adaptors. These adaptors are designed in such a way that they result in an in frame fusion between the 3'-end of the *gox* gene and the restored V<sub>H</sub> gene fragment, optionally intersected with a DNA sequence encoding a peptide linker sequence.

An example of these designed adaptors is:

MluI
XhoI  
CGCGTCCATGCAGTCCTCAGGTGGATCATCCCAGGTGAACTGC  
 25      AGGTACGTCAGGAGTCCACCTAGTAGGGTCCACTTTGACGAGCT  
          S M Q | S S G G S S | Q V K L L E  
 (see SEQ. ID. NO: 57-59)

which encodes for the last amino acids of GOX, an SSGGSS linker sequence (see SEQ. ID. NO: 62) and the N-terminal amino acids of the Camel V<sub>II</sub> fragment of pB3. Instead of the SSGGSS linker (see SEQ. ID. NO: 62) it is possible to use other  
30 linkers such as the repeated sequence linkers described in the above indicated European patent application 92402326.0, e.g. a repeated sequence Pro-X, with X being any amino acid, but preferably Gln, Lys or Glu, the sequence containing

advantageously at least 3 repeats of Pro-X and especially a fragment composed of a 12-fold repeat of the sequence Pro-X.

In case the about 435 bp *XhoI-HindIII* fragment of pUR4433M is used in  
5 combination with the above described adaptor, this would result in pGOX2-03M. From this plasmid a *Sall-AflII* fragment of about 2.1 kb encoding the C-terminal part of glucose oxidase followed by the linker peptide, the Camel V<sub>H</sub> fragment of pB3 and finally the Myc tail.

Upon digesting pAW14B-GOX partially with *BbsI*, and with *AflII*, the about 7.4 kb  
10 vector fragment can be isolated. This fragment contains the xylanase promoter, the DNA sequence encoding the N-terminal part of glucose oxidase and the xylanase promoter. Due to the digestion with *BbsI*, a *Sall* sticky end is created, corresponding with the *Sall* restriction site originally present in the *gox* gene. Ligation of the *Sall-AflII* vector fragment with the about 2.1 kb *Sall-AflII* fragment of pGOX2-03M,  
15 resulting in pUR4441M. This expression plasmid encodes for a single chain polypeptide comprising the glucose oxidase enzyme, the (functionalized) Camel V<sub>H</sub> fragment and the Myc tail.

Introduction of this type of expression plasmids in *Aspergillus* can be achieved essentially as described in example 6.

20 As the naturally occurring glucose oxidase is a homodimeric enzyme, it might be expected that a fusion protein, comprising glucose oxidase and an antibody fragment as a C-terminal extension, has an increased avidity for the antigen/antibody binding, if this fusion protein is produced as a homodimer. Alternatively, it is possible to produce heterodimers, consisting of one glucose oxidase molecule connected to a V<sub>H</sub>  
25 fragment and one wild type glucose oxidase molecule. This can be achieved by producing with the same strain both wild type glucose oxidase and the fused glucose oxidase-V<sub>H</sub> fragment, or by mixing the two different homodimers produced by different strains under conditions whereby the mixture of dimers are dissociated and subsequently associated.

## Example 8 Engineering of *Camelidae* V<sub>H</sub> fragments

### 8.1 Random and targeted random mutagenesis.

After expressing a number of different *Camelidae* V<sub>H</sub> fragments in lower eukaryotic host organisms as described above, or in prokaryotes, fragments produced in relative  
 5 higher amounts can be selected. Upon subjecting the *Xho*I-*Bst*EII gene fragments to a (targeted) random mutagenesis procedure, it might be possible to further improve special characteristics of the V<sub>H</sub> fragment, e.g. further improvement of the production level, increased stability or increased affinity.

To this end the following procedure might be followed.

- 10 Upon replacing the polylinker of the phagemid vector pHEN1 (Hoogenboom *et al.*, 1991) located on a *Nco*I-*Not*I fragment by a new polylinker having the following sequence:

15 

<i>Nco</i> I	<i>Xho</i> I	<i>Bst</i> EII	<i>Not</i> I
<u>CATGGCCAGGTGAAACTGCTCGAGTAAGTGACTAAGGTCACCGTCTCCTCAGC</u>			
CGGTCCACTTTGACGAGCTCATTCAGTATCCAGTGGCAGAGGAGTCGCCGG			

(see SEQ. ID. NO: 60-61) it becomes possible to introduce *Xho*I-*Bst*EII fragments encoding truncated *Camelidae* V<sub>H</sub> fragments in the phagemid.

- Following mutagenesis of the V<sub>H</sub> encoding sequence (random mutagenesis) or a  
 20 specific part thereof (targeted random mutagenesis), the mutated V<sub>H</sub> fragments can be expressed and displayed on the phage surface in essentially the same way as described by Hoogenboom *et al.* (1991). Selecting phages displaying (mutant) V<sub>H</sub> fragments, can be done in different ways, a number of which are described by Marks *et al.* (1992). Subsequently, the mutated *Xho*I-*Bst*EII fragments can be isolated from  
 25 the phagemid and introduced into expression plasmids for yeast or fungi as described in previous examples.

Upon producing the mutant V<sub>H</sub> fragments by these organisms, the effects of the mutations on production levels, V<sub>H</sub> fragment stability or binding affinity can be evaluated easily and improved V<sub>H</sub> fragments can be selected.

- 30 Obviously, a similar route can be followed for larger antibody fragments. With similar procedures the activity of catalytic antibodies can be improved.

## 8.2 Site-directed or designed mutagenesis

As an alternative to the methods described above in Example 8.1 it is possible to use the well-known technique of site-directed mutagenesis. Thus, designed mutations, preferably based on molecular modelling and molecular dynamics, can be introduced in the  $V_H$  fragments, e.g. in the framework or in the CDRs.

## 8.3 Construction $V_H$ fragments with regulatable binding efficiencies.

For particular applications, the possibility to regulate the binding capacity of antibody fragments might be necessary. The introduction of metal ion binding sites in proteins is known from the literature e.g. Pessi *et al.* (1993). The present inventors envisage that the introduction of a metal binding site in an antibody fragment by rational design can result in a regulatable antibody fragment, when the metal binding site is introduced at a position such that the actual binding of the metal ion results in a conformational change in the antibody fragments due to which the binding of the antigen to the antibody fragment is influenced. Another possibility is that the presence of the metal prevents antigen binding due to steric hindrance.

## 8.4 Grafting of CDR regions on the framework fragments of a Camelidae $V_H$ fragment.

Grafting of CDR fragments onto framework fragments of different antibodies or fragments thereof is known from the literature (see Jones *et al.* (1986), WO-A-92/15683, and WO-A-92/01059). In these cases the CDR fragments of murine antibody fragments were grafted onto framework fragments of human antibodies. The sole rationale behind the "humanization" was to increase the acceptability for therapeutic and/or diagnostic applications in human.

Essentially the same approach can however also be used for a totally different purpose. Although antibody fragments share some homology in the framework areas, the production levels vary considerably.

Once an antibody or an antibody fragment, e.g. a Camelidae  $V_H$  fragment, has been identified, which can be produced to high levels by a production organism of interest, this antibody (fragment) can be used as a starting point to construct "grafted" antibody (fragments), which can be produced in high levels and have an

other specificity as compared to the original antibody (fragment). In particular cases it might be necessary to introduce some modifications in the framework fragments as well in order to obtain optimal transitions between the framework fragments and the CDR fragments. For the determination of the optimal transitions molecular dynamics and molecular modelling can be used.

To this end a synthetic gene, encoding the "grafted V<sub>H</sub>" fragment, can be constructed and introduced into an expression plasmid. Obviously it is possible to adapt the codon usage to the codons preferred by the host organism.

For optimization of the "grafted V<sub>H</sub>" fragment, the procedure as described in example 8.1 can be followed.

(C) OPERATING SYSTEM: PC-DOS/MS-DOS  
(D) SOFTWARE: PatentIn Release #1.0, Version #1.25 (EPO)  
  
60 (2) INFORMATION FOR SEQ ID NO: 1:  
  
(i) SEQUENCE CHARACTERISTICS:  
65 (A) LENGTH: 5 amino acids  
(B) TYPE: amino acid  
(C) STRANDEDNESS: single  
(D) TOPOLOGY: linear

(ii) MOLECULE TYPE: protein

(xi) SEQUENCE DESCRIPTION: SEQ ID NO: 1:

5     Ala Pro Glu Leu Leu  
      1                   5

(2) INFORMATION FOR SEQ ID NO: 2:

10     (i) SEQUENCE CHARACTERISTICS:  
       (A) LENGTH: 5 amino acids  
       (B) TYPE: amino acid  
       (C) STRANDEDNESS: single  
15       (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: protein

(xi) SEQUENCE DESCRIPTION: SEQ ID NO: 2:

20     Ala Pro Glu Leu Pro  
      1                   5

(2) INFORMATION FOR SEQ ID NO: 3:

(i) SEQUENCE CHARACTERISTICS:  
   (A) LENGTH: 21 base pairs  
   (B) TYPE: nucleic acid  
30    (C) STRANDEDNESS: single  
      (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: DNA (genomic)

35     (xi) SEQUENCE DESCRIPTION: SEQ ID NO: 3:

CGCCATCAAG GTACCA GTTG A 21

(2) INFORMATION FOR SEQ ID NO: 4:

(i) SEQUENCE CHARACTERISTICS:  
   (A) LENGTH: 89 amino acids  
45    (B) TYPE: amino acid  
      (C) STRANDEDNESS: single  
      (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: protein

50     (vii) IMMEDIATE SOURCE:  
       (B) CLONE: human heavy chain framework (subgroup III)  
              (Xaa = CDR1, Xaa Xaa = CDR2 and Xaa Xaa Xaa = CDR3)

55     (xi) SEQUENCE DESCRIPTION: SEQ ID NO: 4:

      Glu Val Gln Leu Val Glu Ser Gly Gly Gly Leu Val Gln Pro Gly Gly  
      1                   5                   10                   15

60     Ser Leu Arg Leu Ser Cys Ala Ala Ser Gly Xaa Trp Val Arg Gln Ala

\*\*\*\_\*\*\*

C L A I M S

1. A process for the production of an antibody or a fragment or functionalized fragment thereof using a transformed lower eukaryotic host containing an  
5 expressible DNA sequence encoding the antibody or (functionalized) fragment thereof, wherein the antibody or (functionalized) fragment thereof is derived from a heavy chain immunoglobulin of *Camelidae* and is devoid of light chains, and wherein the lower eukaryotic host is a mould or a yeast.
- 10 2. A process according to claim 1, in which the mould belongs to the genera *Aspergillus* or *Trichoderma*.
3. A process according to claim 1, in which the yeast belongs to the genera *Saccharomyces*, *Kluyveromyces*, *Hansenula*, or *Pichia*.
- 15 4. A process according to claim 1, in which the heavy chain fragment at least contains the whole variable domain.
5. A process according to claim 1, in which the antibody or (functionalized)  
20 fragment thereof derived from a heavy chain immunoglobulin of *Camelidae* comprises a complementary determining region (CDR) different from the CDR belonging to the natural antibody ex *Camelidae* grafted on the framework of the variable domain of the heavy chain immunoglobulin ex *Camelidae*.
- 25 6. A process according to claim 1, in which the immunoglobulin to be produced is a catalytic antibody raised in *Camelidae*.
7. A process according to claim 1, in which the functionalized antibody or fragment thereof comprises a fusion protein of both a heavy chain immunoglobulin from  
30 *Camelidae* or a fragment thereof and another polypeptide.

8. A process according to claim 1, in which the DNA sequence encodes a modified heavy chain immunoglobulin or (functionalized) fragment thereof derived from *Camelidae* and being devoid of light chains, and is made by random or directed mutagenesis or both.

5

9. A process according to claim 8, in which the resulting immunoglobulin or (functionalized) fragment thereof is modified such that

- it is better adapted for production by the host cell, or
  - it is optimized for secretion by the lower eukaryotic host into the
- 10 fermentation medium, or
- its binding properties ( $k_{on}$  and  $k_{off}$ ) are optimized, or
  - its catalytic activity is improved, or
  - it has acquired a metal chelating activity, or
  - its physical stability is improved.

15

10. A composition containing a product produced by a process as claimed in any one of claims 1-9.

11. New product obtainable by a process as claimed in any one of claims 1-9.

20

12. A composition containing a new product as claimed in claim 11.

## INTERNATIONAL SEARCH REPORT

International Application No

PCT/EP 94/01442

A. CLASSIFICATION OF SUBJECT MATTER  
 IPC 5 C12N15/13 C07K15/28 A61K39/395

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)  
 IPC 5 C12N C07K A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	EP,A,0 256 421 (PHILLIPS PETROLEUM COMPANY) 24 February 1988 cited in the application see the whole document ---	1,3
P,X	NATURE vol. 363, no. 6428, 3 June 1993, LONDON, GB pages 446 - 448 C. HAMERS-CASTERMAN ET AL. 'Naturally occurring antibodies devoid of light chains.' cited in the application see the whole document --- -/--	1,4, 10-12

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

## \* Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

Date of the actual completion of the international search

19 August 1994

Date of mailing of the international search report

26 -08- 1994

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2
